We study the Higgs sector of the minimal supersymmetric standard model extended with vector-like quarks, at the one-loop level. The radiative corrections to the tree-level masses of the scalar Higgs bosons are calculated by including the contributions from the loops of top quark, vector-like quarks, and their scalar superpartners, for a reasonable parameter region. We find that the mass of the lightest scalar Higgs boson at the one-loop level should be larger than 85 GeV, if we take into account the negative experimental result for the Higgs search at LEP2. As the radiative corrections are calculated in some detail, we also find that the mass of the lightest scalar Higgs boson at the one-loop level is bounded from above at 280 GeV, This upper bound is increased from a previous result. It may provide a wider possibility for the future collider experiments to discover the lightest scalar Higgs boson of this model.

PACS numbers:

I. INTRODUCTION

Although the minimal supersymmetric standard model (MSSM) [1-5] is the simplest version among the supersymmetric extensions of the Standard Model (SM), with just two Higgs doublets, there are some arguments that it should be extended [6]. One of the motivations to extend the MSSM may be the fine-tuning problem, which states that the radiative corrections to the tree-level mass of the lightest scalar Higgs boson in the MSSM should be large enough to be consistent with the experimental lower bound on the Higgs boson mass at LEP2, around 114 GeV. If the radiative corrections are not large enough, the lightest scalar Higgs boson in the MSSM might face the difficulty of incompatibility with experiments.

In the next-to-MSSM [7-10], where an additional Higgs singlet is introduced to the MSSM, the fine-tuning problem may be alleviated by the contributions from the Higgs singlet. The presence of the Higgs singlet increases the upper bound on the tree-level mass of the lightest scalar Higgs boson in the next-to-MSSM up to about 115 GeV, and thus the radiative corrections need not be large enough to be consistent with LEP2 data [11-38].

The burden of the fine tuning in the MSSM might also be reduced by adding extra quarks, such as the sequential quarks or the vector-like quarks. If the additional quarks are those of the fourth generation, with masses at about 400 GeV, it has been shown that the mass of the lightest scalar Higgs boson in the MSSM might increase up to 400 GeV [39]. If the additional quarks are vector-like quarks, as proposed about two decades ago by Moroi and Okada [40,41], the fine tuning problem might be solved by the radiative corrections due to the contributions from the vector-like quarks and the vector-like scalar quarks. The vector-like quarks and their superpartners increase the mass of the lightest scalar Higgs boson well above the LEP2 bound, without requiring a large SUSY breaking scale as 2 TeV [40-46].

Recently, in the extension of the MSSM with vector-like quarks, Martin has investigated the one-loop corrections to the mass of the lightest scalar Higgs boson [46]. He has shown that the radiative corrections due to the vector-like quarks and vector-like scalar quarks may be as large as about 55 GeV, if the mass of the lightest scalar Higgs boson before correction is 110 GeV. His result has been obtained by neglecting some soft SUSY breaking parameters to simplify the 4×4 mass matrix of the vector-like scalar quarks into two 2×2 submatrices, and assuming that the weak eigenstates and the mass eigenstates of the vector-like quarks are identical.

In this article, we show that the one-loop mass of the lightest scalar Higgs boson may be even as large as 280 GeV if we carry out the calculations without the above simplifications assumed in Ref. [46], by taking into account the contributions from top quark and vector-like quarks and their scalar superpartners at the one-loop level. The masses of the vector-like quarks are assumed to lie in the range of 300 GeV to 550 GeV, and the masses of the vector-like scalar quarks in the range of 200 GeV to 910 GeV. The lower bound on the mass of the lightest scalar Higgs boson in this model is determined such that it should not have been discovered at LEP2 with a mass smaller than its lower bound. The negative experimental result for the Higgs search at LEP2 set the lower bound on the mass of the lightest scalar Higgs boson as 85 GeV. We may note that, since the mass of the lightest scalar Higgs boson can be sufficiently large, there are wide regions in the parameter space of the extensions of the MSSM with vector-like quarks which shall be examined by the Higgs search in future high-energy collider experiments.

II. HIGGS BOSONS

Martin have investigated several versions of extensions of the MSSM with the vector-like matters in Ref. [46]. To be specific, we study the QUE model among them, where three vector-like chiral fields are introduced to the MSSM. These vector-like fields transform under $SU(3)_C \times SU(2)_L \times U(1)$ as

$$\begin{array}{ll} \mathcal{Q} = (\mathbf{3}, \mathbf{2}, 1/6), & \bar{\mathcal{Q}} = (\bar{\mathbf{3}}, \mathbf{2}, -1/6), \\ \mathcal{U} = (\mathbf{3}, \mathbf{1}, 2/3), & \bar{\mathcal{U}} = (\bar{\mathbf{3}}, \mathbf{1}, -2/3), \\ \mathcal{E} = (\mathbf{1}, \mathbf{1}, -1), & \bar{\mathcal{E}} = (\bar{\mathbf{1}}, \mathbf{1}, 1), \end{array} \tag{1}$$

where $\mathcal{Q}$, $\bar{\mathcal{Q}}$, $\mathcal{U}$, and $\bar{\mathcal{U}}$ are the vector-like quark fields, while $\mathcal{E}$ and $\bar{\mathcal{E}}$ are the vector-like lepton fields. In terms of physical particles, this model has, in addition to the SM quarks and leptons, V_1 and V_2, quarks with charge $+2/3$, B', a quark with charge $-1/3$, and a charged lepton L', together with their scalar partners $\tilde{V}_i$ $(i = 1, 2, 3, 4)$, $\tilde{B}_i$ $(i = 1, 2)$, and $\tilde{L}_i$ $(i = 1, 2)$.

The superpotential of our model may be written as

$$\begin{aligned} \mathcal{W} &= \mathcal{W}_{\rm MSSM} + M_Q \mathcal{Q}\bar{\mathcal{Q}} + M_U \mathcal{U}\bar{\mathcal{U}} + M_E \mathcal{E}\bar{\mathcal{E}} \\ &\quad + k\mathcal{H}_u \mathcal{Q}\bar{\mathcal{U}} - h\mathcal{H}_d \bar{\mathcal{Q}}\mathcal{U} \ , \end{aligned} \tag{2}$$

where M_Q, M_U, and M_E are the soft SUSY breaking masses of the vector-like sector, and k and h are Yukawa coupling coefficients to the Higgs fields H_u and H_d, with the weak hypercharge $+1/2$ and $-1/2$, respectively.

The tree-level Higgs potential of our model is the same as the Higgs potential of the MSSM at the tree level. It is given as

$$\begin{aligned} V_0 &= m_u^2 |H_u|^2 + m_d^2 |H_d|^2 - \left(m_{ud}^2 H_u H_d + \text{H.c.} \right) \\ &\quad + \frac{1}{8} ({g_1}^2 + g_2^2) \left(|H_u|^2 - |H_d|^2 \right)^2 \ , \end{aligned} \tag{3}$$

where m_u, m_d, and m_{ud} are the mass parameters, $H_d^T = (H_d^0, H_d^-)$ and $H_u^T = (H_u^+, H_u^0)$ are two Higgs doublets, and g_1 and g_2 are respectively the gauge coupling coefficients for $U(1)$ and $SU(2)$. There are two neutral scalar Higgs bosons and a neutral pseudoscalar Higgs bosons in the MSSM. The vacuum expectation values (VEVs) developed by two neutral scalar Higgs bosons are denoted as $v_d = \langle H_d \rangle$ and $v_u = \langle H_u \rangle$, and their ratio is repesented by $\tan\beta = v_u / v_d$. In this article, we would not consider the CP mixing between the scalar and pseudoscalar Higgs bosons. Thus, the vacuum expectation values of the neutral Higgs fields as well as the parameters of the Higgs potential are all real.

Two mass parameters m_d and m_u can be eliminated by the minimum equations with respect to the scalar Higgs fields. Thus, just two paramaters, m_{ud} and $\tan\beta$, describe the tree-level masses of the scalar Higgs bosons. They are given by the eigenvalues of the tree-level 2×2 mass matrix, M^0, for the scalar Higgs bosons. The matrix elements of M^0 are given explicitly as

$$\begin{aligned} M_{11}^0 &= m_Z^2 \cos^2\beta + m_{ud}^2 \tan\beta \ , \\ M_{22}^0 &= m_Z^2 \sin^2\beta + m_{ud}^2 \cot\beta \ , \\ M_{12}^0 &= - m_Z^2 \cos\beta \sin\beta - m_{ud}^2 \ , \end{aligned} \tag{4}$$

where $m_Z^2 = (g_1^2 + g_2^2) v^2/2$ is the squared mass of Z boson, with $v = \sqrt{v_d^2 + v_u^2} = 175$ GeV. Note that the tree-level mass of the lightest scalar Higgs boson is smaller than Z boson mass.

In order to study the radiative corrections to the tree-level Higgs boson mass, we evaluate the Higgs potential at the one-loop level. The one-loop effective potential is given by the effective pottential approximation as [47]

$$V_1 = \sum_l \frac{n_l \mathcal{M}_l^4}{64\pi^2} \left[\log \frac{\mathcal{M}_l^2}{\Lambda^2} - \frac{3}{2} \right] \ , \tag{5}$$

where Λ is the renormalization scale in the modified minimal subtraction scheme, $\mathcal{M}_l$ are the field-dependent masses of quarks and scalar quarks, and n_l are the degrees of freedom arising from color, charge, and spin factors of the particles in the loops, hence, $n_l = -12$ for quarks and $n_l = 6$ for scalar quarks. We take into account top quark, vector-like quarks and their scalar superpartners, as their contributions are significant for the mass of the lightest scalar Higgs boson at the one-loop level in our analysis. The full Higgs potential at the one-loop level is thus

$$V = V_0 + V_1 \ . \tag{6}$$

The masses of the scalar top quarks after electroweak symmetry breaking may be expressed as

$$m_{\tilde{t}_1, \tilde{t}_2}^2 = \frac{(m_Q^2 + m_T^2)}{2} + m_t^2 \mp \sqrt{X_t} \ , \tag{7}$$

with

$$X_t = \left[\frac{m_Q^2 - m_T^2}{2} \right]^2 + m_t^2 \left(A_t - \mu \cot\beta \right)^2 \ , \tag{8}$$

where m_Q and m_T are soft SUSY breaking masses, $m_t = h_t v_u$ is the mass of top quark, with h_t being the Yukawa coupling coefficient for top quark, A_t is the trilinear SUSY breaking mass parameter, and μ is a parameter with mass dimension. Note that X_t represents the mixing between the left-handed and the right-handed scalar top quarks.

Next, let us study the vector-like sector of our model. We adapt the notation of Re. [46]. The mass matrix for the vector-like quarks at the tree level is given by

$$m_F^2 = \left(\begin{array}{cc} \mathcal{M}_F \mathcal{M}_F^\dagger & 0 \\ 0 & \mathcal{M}_F^\dagger \mathcal{M}_F \end{array} \right) \ , \tag{9}$$

with

$$\mathcal{M}_F = \left(\begin{array}{cc} M_Q & k v_u \\ h v_d & M_U \end{array} \right) \ , \tag{10}$$

The squared masses of the two vector-like quarks, $m_{V_i}^2$ $(i = 1, 2)$, are given by the doubly degenerate eigenvalues of m_F^2.

The mass matrix of the vector-like scalar quarks is given by

$$M^2_{\tilde{V}} = m^2_F + \begin{pmatrix} m_1^2 & 0 & b_\Phi & A_k v_u - k\mu v_d \\ 0 & m_2^2 & A_h v_d - h\mu v_u & b_\phi \\ b_\Phi & A_h v_d - h\mu v_u & m_3^2 & 0 \\ A_k v_u - k\mu v_d & b_\phi & 0 & m_4^2 \end{pmatrix} , \tag{11}$$

where b_Φ and b_ϕ are the soft SUSY breaking parameters with mass-square dimension, m_1, m_2, m_3 and m_4 are the soft SUSY breaking masses and A_k and A_h are the trilinear mass parameters. We assume that they are all real and yield real eigenvalues. We note that, unlike Ref. [46], $M^2_{\tilde{V}}$ cannot decomposed into two 2×2 submatrices, since we keep non-zero off-diagonal elements in m^2_F. Moreover, we do not neglect b_Φ and b_ϕ. This is the main difference from Ref. [46].

Now, we apply the above formulae for the tree-level masses of top quark, vector-like quarks, and their scalar superpartners into the one-loop effective Higgs potential in order to evaluate their contributions to the mass of the lightest scalar Higgs boson. The masses of two scalar Higgs bosons at the one-loop level are given as

$$m^2_{S_1,S_2} = \frac{1}{2}\left[\mathrm{Tr}\Big(M\Big) \mp \sqrt{\Big(\mathrm{Tr}(M)\Big)^2 - 4\mathrm{det}\Big(M\Big)}\right] , \tag{12}$$

where S_1 is the lighter scalar Higgs boson as we define $m_{S_1} < m_{S_2}$, and M is the 2×2 squared mass matrix for the scalar Higgs bosons at the one-loop level.

It is convenient to decompose M as

$$M = M^0 + M^t + 2M^V + M^{\tilde{V}} , \tag{13}$$

where M^0 is the tree-level mass matrix, and M^t, M^V, and $M^{\tilde{V}}$ respectively denotes the radiative corrections due to the contributions from the loops of top quark and scalar top quarks, from the loops of the vector-like quarks, and from the loops of the vector-like scalar quarks. Note that the factor of 2 on M^V shows that two vector-like quarks produce the same radiative corrections due to the degeneracy between them. Let us calculate each of these radiative corrections.

The radiative corrections due to the loops of top quark and scalar top quarks are given as $(i, j = 1, 2)$

$$\begin{aligned} M^t_{ij} &= \frac{3W^t_i W^t_j}{32\pi^2 v^2}\frac{g(m^2_{\tilde{t}_1}, m^2_{\tilde{t}_2})}{(m^2_{\tilde{t}_2} - m^2_{\tilde{t}_1})^2} + \frac{3A^t_i A^t_j}{32\pi^2 v^2}\log\left(\frac{m^2_{\tilde{t}_1} m^2_{\tilde{t}_2}}{\Lambda^4}\right) \\ &\quad + \frac{3}{32\pi^2 v^2}(W^t_i A^t_j + A^t_i W^t_j)\frac{\log(m^2_{\tilde{t}_2}/m^2_{\tilde{t}_1})}{(m^2_{\tilde{t}_2} - m^2_{\tilde{t}_1})} \\ &\quad + D^t_{ij} , \end{aligned} \tag{14}$$

where

$$g(m^2_x, m^2_y) = \frac{m^2_y + m^2_x}{m^2_x - m^2_y}\log\frac{m^2_y}{m^2_x} + 2 , \tag{15}$$

$$\begin{aligned} D^t &= -\frac{3}{16\pi^2 v^2}\left(\frac{m^2_t \mu A_t \cos\varphi}{\sin^3\beta\cos\beta}\right) f(m^2_{\tilde{t}_1},\ m^2_{\tilde{t}_2}) , \\ D^t_{11} &= \sin^2\beta D^t , \\ D^t_{22} &= \cos^2\beta D^t , \\ D^t_{12} &= -\cos\beta\sin\beta D^t , \end{aligned} \tag{16}$$

and

$$\begin{aligned} A^t_1 &= 0 , \\ A^t_2 &= \frac{2m^2_t}{\sin\beta} , \\ W^t_1 &= \frac{2m^2_t\mu(\mu\cot\beta - A_t)}{\sin\beta} , \\ W^t_2 &= \frac{2m^2_t A_t(A_t - \mu\cot\beta)}{\sin\beta} , \end{aligned} \tag{17}$$

with

$$f(m^2_x, m^2_y) = \frac{1}{(m^2_y - m^2_x)}\left[m^2_x\log\frac{m^2_x}{\Lambda^2} - m^2_y\log\frac{m^2_y}{\Lambda^2}\right] + 1 . \tag{18}$$

The radiative corrections due to the loops of the vector-like quarks are given as $(i, j = 1, 2)$

$$\begin{aligned} M^V_{ij} &= \frac{3W^V_i W^V_j}{32\pi^2 v^2}\frac{g(m^2_{V_1}, m^2_{V_2})}{(m^2_{V_2} - m^2_{V_1})^2} \\ &\quad + \frac{3A^V_i A^V_j}{32\pi^2 v^2}\log\left(\frac{m^2_{V_1} m^2_{V_2}}{\Lambda^4}\right) \\ &\quad + \frac{3}{32\pi^2 v^2}(W^V_i A^V_j + A^V_i W^V_j)\frac{\log(m^2_{V_2}/m^2_{V_1})}{(m^2_{V_2} - m^2_{V_1})} \\ &\quad + D^v_{ij} , \end{aligned} \tag{19}$$

where

$$\begin{aligned} A^V_1 &= vv_d h^2, \\ A^V_2 &= vv_u k^2, \\ W^V_1 &= vv_d h^2(4M^2_Q + 5v^2_d h^2 - v^2_u k^2) , \\ W^V_2 &= vv_u k^2(v^2_u k^2 - v^2_d h^2) , \end{aligned} \tag{20}$$

where m_{V_i} $(i = 1, 2)$ are the masses of the vector-like quarks.

The radiative corrections due to the loops of the vector-like scalar quarks are given as $(i, j = 1, 2)$

$$M^{\tilde{V}}_{ij} = \sum_{k=1}^{4}\frac{3m^2_{\tilde{V}_k}}{32\pi^2}\left(\log\frac{m^2_{\tilde{V}_k}}{\Lambda^2} - 1\right)\frac{\partial^2 m^2_{\tilde{V}_k}}{\partial S_i \partial S_j}$$

$$+\sum_{k=1}^{4}\frac{3}{32\pi^2}\log\frac{m^2_{\tilde{V}_k}}{\Lambda^2}\left(\frac{\partial m^2_{\tilde{V}_k}}{\partial S_i}\right)\left(\frac{\partial m^2_{\tilde{V}_k}}{\partial S_j}\right) \quad (21)$$

where the first-order derivative $\partial m^2_{\tilde{V}_k}/\partial S_i$ is given explicitly by

$$\frac{\partial m^2_{\tilde{V}_k}}{\partial S_i} = -\frac{A_i m^6_{\tilde{V}_k} + B_i m^4_{\tilde{V}_k} + C_i m^2_{\tilde{V}_k} + D_i}{4m^6_{\tilde{V}_k} + 3Am^4_{\tilde{V}_k} + 2Bm^2_{\tilde{V}_k} + C}, \quad (22)$$

and the second-order derivative $\partial^2 m^2_{\tilde{V}_k}/\partial S_i \partial S_j$ by

$$\begin{aligned}
\frac{\partial^2 m^2_{\tilde{V}_k}}{\partial S_i \partial S_j} &= -\frac{A_{ij} m^6_{\tilde{V}_k} + B_{ij} m^4_{\tilde{V}_k} + C_{ij} m^2_{\tilde{V}_k} + D_{ij}}{4m^6_{\tilde{V}_k} + 3Am^4_{\tilde{V}_k} + 2Bm^2_{\tilde{V}_k} + C} \\
&+ \frac{(A_i m^6_{\tilde{V}_k} + B_i m^4_{\tilde{V}_k} + C_i m^2_{\tilde{V}_k} + D_i)}{(4m^6_{\tilde{V}_k} + 3Am^4_{\tilde{V}_k} + 2Bm^2_{\tilde{V}_k} + C)^2} \\
&\times (3A_j m^4_{\tilde{V}_k} + 2B_j m^2_{\tilde{V}_k} + C_j) \\
&+ \frac{(A_j m^6_{\tilde{V}_k} + B_j m^4_{\tilde{V}_k} + C_j m^2_{\tilde{V}_k} + D_j)}{(4m^6_{\tilde{V}_k} + 3Am^4_{\tilde{V}_k} + 2Bm^2_{\tilde{V}_k} + C)^2} \\
&\times (3A_i m^4_{\tilde{V}_k} + 2B_i m^2_{\tilde{V}_k} + C_i) \\
&- \frac{(12m^4_{\tilde{V}_k} + 6Am^2_{\tilde{v}_k} + 2B)}{(4m^6_{\tilde{V}_k} + 3Am^4_{\tilde{V}_k} + 2Bm^2_{\tilde{v}_k} + C)^3} \\
&\times (A_i m^6_{\tilde{V}_k} + B_i m^4_{\tilde{V}_k} + C_i m^2_{\tilde{V}_k} + D_i) \\
&\times (A_j m^6_{\tilde{V}_k} + B_j m^4_{\tilde{V}_k} + C_j m^2_{\tilde{V}_k} + D_j) \quad (23)
\end{aligned}$$

The explicit expressions for the various coefficients in the above formulae are given in the Appendices: A, B, and C in Appendix I, A_i, B_i, C_i, and D_i $(i = 1, 2)$ in Appendix II and A_{ij}, B_{ij}, C_{ij}, and D_{ij}, $(i, j = 1, 2)$ in Appendix III.

III. NUMERICAL ANALYSIS

For numerical analysis, we simplify our formulae by assuming that $k = h$, $M_Q = M_U$, $m_Q = m_T$, $m_1 = m_2 = m_3 = m_4$, and $b_\phi = b_\Phi$. We set $m_1 = m_2 = m_3 = m_4$ as M_ϕ. Note that these simplifications reduce the number of independent parameters, but we are still left with a number of them: m_{du} and $\tan\beta$ in M^0, μ, $m_Q = m_T$, and A_t in M^t, and M_ϕ, k, and b_ϕ in M^V and $M^{\tilde{V}}$. We set the allowed ranges for these parameters as follows: $0 < m_{du}$ (GeV) < 200, $2 < \tan\beta < 30$, $150 < \mu$ (GeV) < 500, $500 < m_Q$ (GeV) < 700, $500 < A_t$ (GeV) < 700, $0 < k < 0.5$, $300 < M_\phi$ (GeV) < 500, $300 < A_k$ (GeV) < 500, and $300 < \sqrt{b_\phi}$ (GeV) < 500. Here, the lower bound on the value of μ is set by the experimental constraint on the chargino system, the upper bound on the Yukawa coupling coefficient of k is set as 0.5 in order to escape the Landau pole at a high energy scale. The upper bound on the SUSY breaking soft masses on the scalar top quark sector are set as 700 GeV because we do not want a large fine tuning. For the top quark mass, we take 171 GeV and assume that it is smaller than the masses of the scalar top quarks. It is obtained that the masses of the vector-like quarks lies in the range of 300 GeV to 550 GeV, and the masses of the vector-like scalar quarks in the range of 200 GeV to 910 GeV.

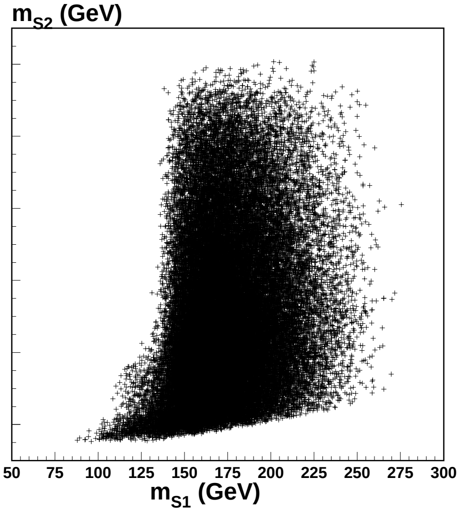

FIG. 1: The distribution of 50,000 points of $(m_{S_1},\ m_{S_2})$, at the one-loop level. The allowed ranges of the parameter values are $0 < m_{du}$ (GeV) < 200, $2 < \tan\beta < 30$, $150 < \mu$ (GeV) < 500, $500 < m_Q$ (GeV) < 700, $500 < A_t$ (GeV) < 700, $0 < k < 0.5$, $300 < M_\phi$ (GeV) < 500, $300 < A_k$ (GeV) < 500, and $300 < \sqrt{b_\phi}$ (GeV) < 500.

Now, let us study G_{ZZS_i} $(i = 1, 2)$, the coupling coefficients of the neutral scalar Higgs bosons to ZZ. In the SM, the corresponding quantity is given as

$$G_{ZZH} = g_2 m_Z / \cos\theta_W \quad (24)$$

where θ_W is the weak mixing angle, and H is the neutral scalar Higgs boson of the SM. We introduce the normalized coupling coefficients $\bar{G}_{ZZS_i}$, which are defined as G_{ZZS_i}/G_{ZZH}. These normalized coupling coefficients satisfy a sum rule:

$$\sum_{i=1}^{2} \bar{G}^2_{ZZS_i} = 1\ . \quad (25)$$

For a given set of parameter values, we calculate the masses of the neutral scalar Higgs bosons at the one-loop level, as well as their normalized coupling coefficients. The LEP2 collaborations have established the model-independent upper bound on the squared coupling coefficient of a neutral scalar boson to a pair of Z bosons, as a function of the mass of the neutral scalar boson [48]. For given mass of S_1, we may compare $\bar{G}_{ZZS_1}$ with the LEP2 result. If $\bar{G}_{ZZS_1}$ is larger than the upper bound set by the LEP2 result, we should increase the mass S_1 until $\bar{G}_{ZZS_1}$ becomes smaller than the LEP2 result. In this way, the lower bound on the mass of S_1 can be established. We examine 50,000 sets of parameter values, and select those sets that satisfy the LEP2 constraint. Those parameter sets yield the masses of the vector-like quarks within the range of 300 to 550 GeV, and the masses of the vector-like scalar quarks in the range of $200 < m_{\tilde{V}_i}$ (GeV) < 910 $(i = 1-4)$.

Our results are shown in Fig. 1, where we plot (m_{S_1}, m_{S_2}) for the selected parameter sets. The lower bound on m_{S_1} is determined by the LEP constraint. One may note in Fig. 1 that the mass of S_1 at the one-loop level may be as large as 280 GeV. This upper bound is reasonably larger than the previous result. In the previous investigation, the mass of the lighter neutral scalar Higgs boson is predicted to be less than 200 GeV [46]. Thus, the upper bound is considerably improved. We attribute this improvement to the difference in approximations. In Ref. [46], it is assumed that $M_Q, M_U \gg kv_u, hv_d$ and $b_\Phi = b_\phi = 0$. Thus, the mass matrix of the vector-like scalar quark is decomposed into two 2×2 submatrices. In our numerical analysis, these approximations are removed though some other simplifications are still used. In other words, we explore a wider region in the parameter space. We note that it is possible to examine the full parameter space of our model if no approximation is made in the numerical analysis. Nevertheless, $m_{S_1} \sim 280$ GeV can relieve the experimental pressure on our model in the sense that it allows the future collider experiments a wider chance to discover the lightest scalar Higgs boson of our model.

IV. CONCLUSIONS

We consider the Higgs sector in an extension of the MSSM with the vector-like quarks and scalar quarks. A reasonable parameter region is set, and the neutral scalar Higgs boson masses are calculated using the effective Higgs potential at the one-loop level, where the radiative corrections due to the contributions from the loops of top quark, scalar top quarks, as well as the vector-like quarks and vector-like scalar quarks, are taken into account. We find that the contributions from the vector-like quark and scalar quark loops are significantly large, if we calculate in detail, with fewer approximations, for a wider parameter space. The mass of the lightest neutral scalar Higgs boson of our model at the one-loop level lies within the range of 85 to 280 GeV, while being consistent with the LEP2 constraint.
